About the NCCN Guidelines for Patients®

Did you know that top cancer centers across the United States work together to improve cancer care? This alliance of leading cancer centers is called the National Comprehensive Cancer Network® (NCCN®).

Cancer care is always changing. NCCN develops evidence-based cancer care recommendations used by health care providers worldwide. These frequently updated recommendations are the NCCN Clinical Practice Guidelines in Oncology (NCCN Guidelines®). The NCCN Guidelines for Patients plainly explain these expert recommendations for people with cancer and caregivers.

These NCCN Guidelines for Patients are based on the NCCN Clinical Practice Guidelines in Oncology (NCCN Guidelines®) for Breast Version 4.2023 – March 23, 2023

1 Breast cancer basics

5 The breast
6 Ductal carcinoma in situ
7 Key points
Ductal carcinoma in situ (DCIS) is found in the cells that line the ducts in the breast. DCIS is stage 0 or noninvasive cancer. This means the cancerous cells are in place (in situ) and have not spread outside the ducts. DCIS is treated to prevent invasive breast cancer, a more advanced form of cancer.

The breast

The breast is an organ and a gland on the chest. The breast is made of milk ducts, fat, nerves, lymph and blood vessels, ligaments, and other connective tissue. Behind the breast is the pectoral (chest) muscle and ribs. Muscle and ligaments help hold the breast in place.

Breast tissue contains glands that can make milk. These milk glands are called lobules. Lobules look like tiny clusters of grapes. Small tubes called ducts connect the lobules to the nipple.

The ring of darker breast skin is called the areola. The raised tip within the areola is called the nipple. The nipple-areola complex (NAC) is a term that refers to both parts.

Lymph is a clear fluid that gives cells water and food. It also helps to fight germs.
Drains from breast tissue into lymph vessels and travels to lymph nodes near your armpit (axilla). Nodes near the armpit are called axillary lymph nodes (ALNs).

**Ductal carcinoma in situ**

Ductal carcinoma in situ (DCIS) or intraductal carcinoma is found in the cells that line the ducts. Ducts are thin tubes that carry milk in the breast. DCIS is noninvasive. Noninvasive means the cancerous cells are in place (in situ) and have not spread. Anyone can develop breast cancer, including those assigned male at birth. Although there are some differences between those assigned male and those assigned female at birth, treatment is very similar for all genders.

DCIS is pre-invasive or pre-cancerous. DCIS is treated to prevent invasive breast cancer, a more advanced form of cancer. Invasive breast cancer is breast cancer that has spread from the milk ducts or milk glands (lobules) into the surrounding breast tissue or nearby lymph nodes. Once outside the ducts or lobules, breast cancer can spread through lymph or blood to lymph nodes or other parts of the body.

**Lobular carcinoma in situ**

Lobular carcinoma in situ (LCIS) is a benign (non-cancerous) condition in which abnormal cells are found in the lobules of the breast. Having LCIS in one breast increases the risk of developing breast cancer in either breast.
Key points

- Anyone can develop breast cancer, but breast cancer occurs more frequently in persons assigned female at birth.
- Inside breasts are lobules, ducts, fat, blood and lymph vessels, ligaments, and connective tissue. Lobules are structures that make breast milk. Ducts carry breast milk from the lobules to the nipple.
- Breast cancer often starts in the ducts or lobules and then spreads into the surrounding tissue.
- Cancerous cells found only inside the ducts or lobules is called noninvasive. Ductal carcinoma in situ (DCIS) is found only in the ducts.
- Invasive breast cancer is cancer that has grown outside the ducts or lobules into surrounding tissue. Once outside the ducts or lobules, breast cancer can spread through lymph or blood to lymph nodes or other parts of the body.

What’s the difference between a screening and diagnostic mammogram?

A mammogram is a picture of the inside of your breast made using x-rays. During a mammogram, the breast is pressed between two plates while you stand in different positions. Multiple x-rays will be taken. A computer combines the x-rays to make detailed pictures.

- Screening mammograms are done on a regular basis when there are no signs or symptoms of breast cancer. Results take a few days.
- Diagnostic mammograms are used for those who have symptoms such as a lump, pain, nipple thickening or discharge, or whose breasts have changed shape or size.
- A radiologist will evaluate the diagnostic mammogram while you wait so if additional testing is needed, it can be done right away.
- Both types of mammograms use low-dose x-rays to examine the breast. They may use either the standard 2-dimensional (2D) digital mammography or 3-dimensional (3D) mammograms known as tomosynthesis.

Testing for DCIS

9 Test results
10 General health tests
11 Imaging tests
12 Biopsy

14 Estrogen receptor status
15 Genetic risk testing
16 Cancer stages
18 Key points
Test results

Results from imaging studies and biopsy will be used to determine your treatment plan. It is important you understand what these tests mean. Ask questions and keep copies of your test results. Online patient portals are a great way to access your test results.

Keep these things in mind:

› Choose a friend, family member, or peer who can drive you to appointments, provide meals, or offer emotional support during diagnosis and treatment.

› Bring someone with you to doctor visits, if possible.

› Write down questions and take notes during appointments. Don’t be afraid to ask your care team questions. Get to know your care team and help them get to know you.

› Get copies of blood tests, imaging results, and reports about the specific type of cancer you have.

› Organize your papers. Create files for insurance forms, medical records, and test results. You can do the same on your computer.

› Keep a list of contact information for everyone on your care team. Add it to your phone. Hang the list on your refrigerator or keep it in a place where someone can access it in an emergency. Keep your primary care physician (PCP) informed of changes to this list.

› Include in your contact list information on the exact type of cancer, as well as any treatment and the date it started.

For possible tests, see Guide 1.

Guide 1
Possible tests

- Medical history and physical exam (H&P)
- Diagnostic mammogram
- Biopsy with pathology review
- Determine estrogen receptor (ER) status
- Genetic counseling, if at risk for hereditary breast cancer
- Breast MRI, as needed
General health tests

Medical history
A medical history is a record of all health issues and treatments you have had in your life. Be prepared to list any illness or injury and when it happened. Bring a list of old and new medicines and any over-the-counter (OTC) medicines, herbal s, or supplements you take. Some supplements interact and affect medicines that your care team may prescribe. Tell your care team about any symptoms you have. A medical history, sometimes called a health history, will help determine which treatment is best for you.

Family history
Some cancers and other diseases can run in families. Your doctor will ask about the health history of family members who are blood relatives. This information is called a family history. Ask family members on both sides of your family about their health issues like heart disease, cancer, and diabetes, and at what age they were diagnosed. It’s important to know the specific type of cancer, or where the cancer started, and if it is in multiple locations, and if they had genetic testing.

Physical exam
During a physical exam, your health care provider may:

- Check your temperature, blood pressure, pulse, and breathing rate
- Check your height and weight
- Listen to your lungs and heart
- Look in your eyes, ears, nose, and throat
- Feel and apply pressure to parts of your body to see if organs are of normal size, are soft or hard, or cause pain when touched.
- Examine your breasts to look for lumps, nipple discharge or bleeding, or skin changes.
- Feel for enlarged lymph nodes in your neck, underarm, and groin.

Clinical breast exam
Clinical breast exam (CBE) is a physical exam of the bare breast performed by a health care provider to check for lumps or other changes. It is done while you are seated and/or lying down. Your provider should take time to palpate (feel) the entire breast, including the armpit. A nurse or assistant might also be in the room during the exam.
Imaging tests

Imaging tests take pictures of the inside of your body. Imaging tests show the primary tumor, or where the cancer started, and look for cancer in other parts of the body.

A radiologist, an expert in interpreting imaging tests, will write a report and send this report to your doctor. The doctor will discuss the results with you. While these reports are available to you through your portal, please wait to discuss these results with the doctor.

**Diagnostic mammogram**

A mammogram is a picture of the inside of your breast. The picture is made using x-rays. A computer combines the x-rays to make detailed pictures. Mammogram results are used to plan treatment.

Diagnostic mammograms look at specific areas of your breasts, which may not be clearly seen on screening mammograms. It is used to see tumor and the size of the tumor(s). Diagnostic mammograms include extra compression in certain areas of the breast, magnification views, or rolling the breast to image additional areas of the breast. Other tests may include a breast MRI or ultrasound.

**Contrast-enhanced mammogram**

Contrast-enhanced mammography is a new technology that uses contrast material to improve the pictures of the inside of the breast. It is sometimes used for those who cannot tolerate a magnetic resonance imaging (MRI) scan.

**Breast MRI**

An MRI scan uses radio waves and powerful magnets to take pictures of the inside of the body. It does not use radiation. If needed, an MRI would be used in addition to a mammogram. Because of the very strong magnets used in the MRI machine, tell the technologist if you have any metal in your body.

In most cases, contrast material will be used to improve the pictures of the breast. Tell your care team if you have had allergic reactions to contrast in the past. This is important. You might be given medicines to avoid the effects of those allergies.

For a breast MRI, a gadolinium-based contrast agent (GBCA)—a rare, heavy metal—is used to enhance the quality of the MRI. There are no harmful effects from GBCA, but it may linger in the body for months to years afterward. Talk to your doctor if you have any concerns.

**Ultrasound**

An ultrasound (US) uses high-energy sound waves to form pictures of the inside of the body. This is similar to the sonogram used for pregnancy. A wand-like probe will be held and moved on your bare breast using gel. It may also be placed below your armpit. Ultrasound is painless and does not use x-rays. It is good at showing small areas of cancer that are near the skin. Sometimes, a breast ultrasound or MRI is used to guide a biopsy.
Biopsy

A biopsy is a procedure that removes a sample of tissue or fluid. The sample is sent to a lab for testing. A pathologist will examine the biopsy for cancer and write a report called a pathology report. Ask questions about your biopsy results and what it means for your treatment.

There are different types of biopsies. Some biopsies are guided using imaging, such as mammogram, ultrasound, or MRI. The primary or main tumor is biopsied first. Other tumors or tumors in different areas may also be biopsied. You may have tissue removed from the breast, lymph nodes, or both.

Types of possible biopsies include:

- **Fine-needle aspiration (FNA) or core biopsy (CB)** uses needles of different sizes to remove a sample of tissue or fluid. In a vacuum-assisted core biopsy (VACB), suction is used to remove the sample special vacuum device.

- **Incisional biopsy** removes a small amount of tissue through a cut in the skin or body.

- **Excisional biopsy** removes the entire abnormal area. This is not the preferred type of biopsy but may be necessary if other methods are not possible or when the biopsy results don’t match the expected findings.

Before biopsies are performed, usually the area is injected with numbing medicine. A core needle biopsy (CNB) removes more than one tissue sample, but usually through the same area on the breast. The samples are small. The needle is often guided into the tumor with imaging. When mammography is used during a biopsy, it is called a stereotactic needle biopsy.

One or more clips may be placed near the breast tumor during a biopsy. The clips are small, painless, and made of metal. They will mark the site for future treatment and imaging. The clips stay in place until surgery. If the area biopsied is benign, the clip will remain in place to mark the biopsy site on future imaging. The clip causes no problems, even if they are left in place for a long time. You will be able to go through airport security and have an MRI with the clip(s) in place.

There are both physical and emotional experiences in having biopsies. You may need to rest and place an ice pack on the biopsy area after the procedure. If you are working or have other commitments, you may want to take the day off to recover emotionally and physically from the experience.
Sentinel lymph node biopsy

A sentinel lymph node (SLN) is the first lymph node or nodes in the armpit that cancer cells are most likely to spread to from a primary tumor. Often, there is more than one sentinel lymph node. Removal of the sentinel lymph nodes during surgery is called a sentinel lymph node biopsy (SLNB or SNB). This procedure is done during surgery such as a mastectomy (surgery to remove the breast) to determine if any cancer cells have traveled to the lymph nodes. The lymph nodes removed are called the sentinel nodes. They may or may not contain any cancer cells. Just because these nodes are removed, it does not mean that they are positive for cancer.

To find the sentinel lymph nodes, a radioactive material and/or blue dye is injected into the breast where it then travels through the lymph channels in the breast to the lymph nodes in the armpit. This helps the surgeon find which of the nodes are the sentinel lymph nodes. Once the nodes are found, those containing the radioactive material or dye are removed and tested by a pathologist.

Biopsy results

Histology is the study of the anatomy (structure) of cells, tissues, and organs under a microscope. It is used to make treatment decisions. Your pathology report will contain information about histology. You may be recommended to have an open biopsy (surgery) to remove (excise) the tumor to confirm histology. Talk to your health care provider for more information on next steps.

Biopsy

In a biopsy, a sample of tumor is removed. There are different types of biopsy. This image shows an ultrasound-guided needle biopsy.
Testing for DCIS  » Estrogen receptor status

Estrogen receptor status

Estrogen is a hormone that plays a role in breast development. A hormone is a substance made by a gland in your body. Your blood carries hormones throughout your body. A receptor is a protein found inside or on the surface of a cell. Substances such as hormones attach (bind) to these receptors. This causes changes within the cell.

Hormones recognize and bind to specific hormone receptors. When hormones, such as estrogen, attach to receptors inside breast cancer cells, they can cause cancer to grow. If found, these estrogen receptors may be targeted for treatment using endocrine therapy.

Immunohistochemistry

Immunohistochemistry (IHC) is a special staining process that involves adding a chemical marker to cells. These cells are then studied using a microscope. IHC can find estrogen receptors in breast cancer cells. A pathologist will measure how many cells have estrogen receptors and the number of estrogen receptors inside each cell. Test results will either be estrogen receptor-positive (ER+) or estrogen receptor-negative (ER-).

Estrogen receptor-positive

In estrogen receptor-positive (ER+) breast cancer, IHC finds estrogen hormone receptors in at least 1 out of every 100 cancer cells. ER+ cancer cells may need estrogen to grow. These cells may stop growing or die with treatment to block estrogen called endocrine therapy.

Estrogen receptor-negative

Estrogen receptor-negative (ER-) breast cancer cells do not have estrogen hormone receptors. These cancer cells do not need estrogen to grow and continue to grow despite treatment to block estrogen.

HER2 testing is not used in the diagnosis and treatment of DCIS.
Genetic risk testing

About 1 out of 10 breast cancers are hereditary. Depending on your family history or other features of your cancer, your health care provider might refer you for hereditary genetic testing to learn more about your cancer. A genetic counselor or trained provider will speak to you about the results. Tests results may be used to guide treatment planning.

Genetic testing is done using blood or saliva (spitting into a cup or a cheek swab). The goal is to look for gene mutations inherited from your biological parents called germline mutations. Some mutations can put you at risk for more than one type of cancer. You can pass these genes on to your children. Also, other family members might carry these mutations. Tell your care team if there is a family history of cancer.

**BRCA tests**

Everyone has BRCA genes. Normal BRCA genes help to prevent tumor growth. They help fix damaged cells and help cells grow normally. BRCA mutations put you at risk for more than one type of cancer. Mutations in BRCA1 or BRCA2 increase the risk of breast, ovarian, prostate, colorectal, pancreatic, and melanoma skin cancers. Mutated BRCA genes can also affect how well some treatments work. These tests might be repeated.

---

**What is your family cancer health history?**

Some cancers and other diseases run in families—those who are related to you through genes passed down from parent to child. This information is called a family health history. Ask blood relatives about their health issues like heart disease, cancer, and diabetes, and at what age they were diagnosed. For relatives who were diagnosed with cancer, ask them (or other relatives if they are no longer living) what type of cancer they had, if they died from the cancer, and at what age the cancer was diagnosed.

Start by asking your parents, siblings, and children. Next, talk to half-siblings, aunts and uncles, nieces and nephews, grandparents, and grandchildren.

Write down what you learn about your family history and share with your health care provider.

Some of the questions to ask include:

- How old were you when each of these diseases and health conditions was diagnosed?
- What is our family’s ancestry – from what countries did our ancestors originate?
Cancer stages

Breast cancer staging is often done twice.

- **Clinical stage** (c) is the rating given before any treatment. It is based on a physical exam, biopsy, and imaging tests. An example might look like cT0 or cN1.

- **Pathologic stage** (p) or surgical stage is determined by examining tissue removed during surgery. An example might be pT1.

A cancer stage is a way to describe the extent of the cancer at the time you are first diagnosed. The American Joint Committee on Cancer (AJCC) created a staging system to determine how much cancer is in your body, where it is located, and what subtype you have. AJCC is just one type of staging system.

Staging is based on a combination of information to reach a final numbered stage. Often, not all information is available at the initial evaluation. More information can be gathered as treatment begins. Doctors may explain your cancer stage in different ways than described next.

**TNM scores**

The tumor, node, metastasis (TNM) system is used to stage breast cancer. In this system, the letters T, N, and M describe different areas of cancer growth. Based on cancer test results, your doctor will assign a score or number to each letter. The higher the number, the larger the tumor or the more the cancer has spread. These scores will be combined to assign the cancer a stage. A TNM example might look like this: T1N0M0 or T1, N0, M0, or for DCIS TisN0M0.

- **T (tumor)** – Depth and spread of the main (primary) tumor(s) in one or both breasts
- **N (node)** – If cancer has spread to nearby (regional) lymph nodes
- **M (metastasis)** – If cancer has spread to distant parts of the body or metastasized

**Lymph nodes**

Lymph, a clear fluid containing cells that help fight infections and other diseases, drains through channels into lymphatic vessels. From here, lymph drains into lymph nodes. Lymph nodes work as filters to help fight infection. Regional lymph nodes are found near the breast in the armpit. It is possible for cancerous cells to travel through lymph to other parts of the body.

**Grade**

Grade describes how abnormal the tumor cells look under a microscope (called histology). Higher-grade cancers tend to grow and spread faster than lower-grade cancers. GX means the grade can’t be determined, followed by G1, G2, and G3. G3 is the highest grade for breast cancers. A low-grade tumor has a low risk of recurrence. A high-grade tumor has a higher risk for recurrence (of cancer returning).

- **GX** – Grade cannot be determined
- **G1** – Low (nuclear grade 1)
- **G2** – Intermediate (nuclear grade 2)
- **G3** – High (nuclear grade 3)
Numbered stages
Numbered stages are based on TNM scores. Stages range from stage 0 to stage 4, with 4 being the most advanced. They might be written as stage 0, stage I, stage II, stage III, and stage IV. For example, DCIS is stage 0 or Tis, N0, M0.

Stage 0 is noninvasive
Noninvasive breast cancer is rated stage 0. DCIS is found only in the ducts (Tis). It has not spread to the surrounding breast tissue, lymph nodes (N0), or distant sites (M0).

Stages 1, 2, and 3 are invasive
Invasive breast cancer is rated stage 1, 2, or 3. It has grown outside the ducts, lobules, or breast skin. Cancer might be in the axillary lymph nodes.

More information on invasive breast cancer can be found at NCCN.org/patientguidelines and on the NCCN Patient Guides for Cancer app.

Stage 4 is metastatic
In stage 4 breast cancer, cancer has spread to distant sites. It can develop from earlier stages. Rarely, your first diagnosis can be stage 4 metastatic breast cancer (called de novo) or it can develop from earlier stages.

More information on metastatic breast cancer can be found at NCCN.org/patientguidelines and on the NCCN Patient Guides for Cancer app.

Breast sections
Quadrants are used to describe tumor location. Each breast is divided into 4 sections or quadrants. They are the upper outer quadrant (near the armpit), the upper inner quadrant (near the center of the body), the lower outer quadrant, and the lower inner quadrant. The nipple area is called the nipple-areola complex (NAC).
Testing for DCIS  » Key points

Key points

- Tests are used to find cancer, plan treatment, and check how well treatment is working.
- You will have a physical exam, including a breast exam, to see if anything feels or looks abnormal.
- Treatment can affect your fertility, the ability to have children.
- Imaging tests take pictures of the inside of your body.
- A diagnostic mammogram includes detailed pictures of both breasts. It is different than a screening mammogram.
- During a biopsy, tissue or fluid samples are removed for testing.
- A sentinel lymph node (SLN) is the first lymph node or nodes in the armpit that cancer cells are most likely to spread to from a primary tumor. A sentinel lymph node biopsy (SNLB) might be done to look for cancer in your lymph node(s).
- A sample from a biopsy of your tumor will be tested for estrogen receptor (ER) status and grade (histology).
- Some breast cancers grow because of estrogen. Testing will be done to see if you have estrogen receptor-positive (ER+) breast cancer.

- About 1 out of 10 breast cancers are hereditary. Depending on your family history or other features of your cancer, your health care provider might refer you for hereditary genetic testing or to speak with a genetic counselor.
- A cancer stage is a way to describe the extent of the cancer at the time you are first diagnosed.
- Breast cancer is often staged twice, before and after surgery.
- Online portals are a great way to access your test results.

Treating DCIS

20  Care team
22  Surgery
24  Radiation therapy
25  Endocrine therapy
27  Clinical trials
28  Supportive care
30  Key points
Treating breast cancer takes a team approach. Treatment decisions should involve a multidisciplinary team (MDT). An MDT is a team of health care and psychosocial care professionals from different professional backgrounds who have knowledge (expertise) and experience in your type of cancer. This team is united in the planning and implementing of your treatment. Ask who will coordinate your care.

Some members of your care team will be with you throughout cancer treatment, while others will only be there for parts of it. Get to know your care team and help them get to know you.

Depending on your diagnosis, the care team might include the following:

- **A diagnostic radiologist** interprets the results of mammograms, ultrasounds, and other imaging tests.
- **A pathologist** analyzes the cells and tissues removed during a biopsy and provides cancer diagnosis, staging, and information about biomarker testing.
- **A surgical oncologist** performs operations to remove cancer.
- **A reconstructive (plastic) surgeon** performs breast reconstruction, if desired, for those who undergo mastectomy.
- **A medical oncologist** treats cancer in adults using systemic therapy such as endocrine therapy.
- **A radiation oncologist** prescribes and delivers radiation therapy to treat cancer.
- **An anesthesiologist** gives anesthesia, a medicine so you do not feel pain during surgery or procedures.
- **Residents and fellows** are doctors who are continuing their training, some to become specialists in a certain field of medicine.
- **Nurse practitioners (NPs) and physician assistants (PAs)** are health care providers. Some of your clinic visits may be done by a nurse practitioner or physician assistant.
- **Oncology nurses** provide your hands-on care, like giving systemic therapy, managing your care, answering questions, and helping you cope with side effects.
- **Oncology pharmacists** are experts in knowing how to use medicines to treat cancer and to manage symptoms and side effects.
- **Palliative care nurses, advanced practice providers (APPs), and physicians** help provide an extra layer of support with cancer-related care.
- **Nutritionists and dietitians** can provide guidance on what foods are most suitable for your condition.
Treating DCIS  » Care team

- **A certified lymphedema therapist** gives a type of massage called manual lymph drainage.

- **Psychologists and psychiatrists** are mental health experts who can help manage issues such as depression, anxiety, or other mental health conditions that can affect how you think and feel.

- **Social workers** help people solve and cope with problems in their everyday lives. Clinical social workers also diagnose and treat mental, behavioral, and emotional issues. The anxiety a person feels when diagnosed with cancer might be managed by a social worker in some cancer centers. They, or other designated professionals, can help navigate the complexities of financial and insurance stresses.

- **A research team** helps to collect research data and coordinate care if you are in a clinical trial. Clinical trials help bring new therapies to patients and advance the treatment for everyone. Consider asking your care team about access to clinical trials.

Your physical, mental, and emotional well-being are important. Help other team members understand:

- How you feel
- What you need
- What is working and what is not

Keep a list of names and contact information for each member of your team. This will make it easier for you and anyone involved in your care to know whom to contact with questions or concerns.

---

If you smoke or vape, seek help to quit

Smoking or vaping nicotine greatly increases your chances of having side effects during and after surgery. Smoking and vaping can limit how well cancer treatment works and prevents wound healing. It also increases your chances of developing other cancers. Marijuana use might also affect the amount of anesthesia used during surgery.

For online support, try these websites:

- [SmokeFree.gov](http://SmokeFree.gov)
- [BeTobaccoFree.gov](http://BeTobaccoFree.gov)
- [CDC.gov/tobacco](http://CDC.gov/tobacco)
Surgery

Surgery is an operation or procedure to remove cancer from the body. Surgery is the main or primary treatment for DCIS. This is only one part of a treatment plan.

When preparing for surgery, seek the opinion of an experienced surgeon. The surgeon should be an expert in performing your type of surgery. Hospitals that perform many surgeries often have better results. You can ask for a referral to a hospital or cancer center that has experience in treating your type of cancer.

The removal of the cancer through surgery can be accomplished in different ways depending on the specific circumstances, such as the size and location of the tumor.

Surgery might be a lumpectomy or mastectomy. It is based on the safest and best way to remove the cancer and your choice. Your preferences about treatment are always important. Make your wishes known.

If you are considering breast reconstruction, surgery requires collaboration between a breast surgeon and a reconstructive (plastic) surgeon. Radiation therapy usually only follows after a lumpectomy. It is important to note that a lymph node biopsy is not done with a lumpectomy.

Goal of surgery

The goal of surgery or tumor resection is to remove all of the cancer. To do so, the tumor is removed along with a rim of normal-looking tissue around its edge called the surgical margin. The surgical margin may look normal during surgery, but cancerous cells may be found when viewed under a microscope by a pathologist. A clear or negative margin (R0) is when no cancer cells are found in the tissue around the edge of the tumor. In a positive margin, cancer cells are found in normal-looking tissue around the tumor.

Surgical margins

The goal of surgery is a cancer-free surgical margin.

- **In a clear or negative margin (R0),** no cancerous cells are found in the tissue around the edge of the tumor.

- **In an R1 positive margin,** the surgeon removes all the visible tumor, but the microscopic margins are still positive for tumor cells. Despite best efforts this can happen.

- **In an R2 positive margin,** the surgeon is unable to remove all the visible tumor or there is metastatic disease.

Your surgeon will look carefully for cancer not only along the surgical margin, but in other nearby areas. Despite best efforts, it is not always possible to find all of the cancer. Sometimes, surgeons can’t safely remove the tumor with a cancer-free margin.

After surgery, you may receive treatment such as radiation to kill any remaining cancer cells. You might have more than one surgery. You might also have a wound drain to prevent fluid from collecting in the body after surgery. These drains are usually removed a few days after surgery.
Lumpectomy

Lumpectomy is the removal of abnormal cells or tumor. It is also called breast-conserving therapy or breast-conserving surgery (BCS). In a lumpectomy, only the DCIS with a small rim of healthy tissue around it will be removed. The surgeon aims to remove all DCIS with at least a 2 millimeter (mm) rim of healthy tissue around it, called a negative, or clear, surgical margin. Having a negative surgical margin will decrease the chance that cancer may return in that area of the breast. You may need more than one surgery to achieve negative margins and ensure all of the cancer was removed.

A lumpectomy is usually followed by radiation therapy to part of or the whole breast. A boost is extra radiation to the tumor area.

The breast might not look the same after a lumpectomy. Speak to your surgeon about how a lumpectomy might affect the look and shape of your breast, and any concerns you have. You can also seek the opinion of a plastic surgeon.

Breastfeeding or chestfeeding

Breastfeeding or chestfeeding following a lumpectomy may be possible. However, after treatments, the breast may produce less milk than before, or none at all. Breastfeeding/chestfeeding is not recommended during active treatment or within 6 months of completing certain types of endocrine therapy.

Total (simple) mastectomy

The dotted line shows where the entire breast is removed. Some lymph nodes under the arm may also be removed.
Mastectomy

A mastectomy is surgery to remove all or part of the breast. Underarm sentinel lymph nodes might be removed. Before removing the breast, the surgeon may do a sentinel lymph node biopsy (SLNB). Sentinel lymph nodes are the first lymph nodes cancer cells are likely to have spread from the primary tumor.

Types of mastectomy include:

- **A total mastectomy or simple mastectomy** is a surgery that removes the whole breast with an aesthetic flat skin closure.

- **A skin-sparing mastectomy** removes the breast but not all of the skin, in order to have breast reconstruction that might include flaps and/or implants.

- **Nipple-sparing mastectomy** preserves the nipple-areola complex (NAC) as well as all of the skin. Not everyone is a candidate for nipple-sparing mastectomy based upon location of cancer, breast size, and breast ptosis (degree of drooping).

Breast reconstruction is an option after a mastectomy. It might be done at the same time as mastectomy (“immediate”) or at some time following the completion of cancer treatment (“delayed”). Breast reconstruction is most commonly done in stages.

Radiation therapy

Radiation therapy (RT) uses high-energy radiation from x-rays, photons, protons, and other sources to kill any remaining cancer cells after surgery. Different types of radiation can be used for DCIS. Most types include several short treatment sessions that are given once daily over a few days to weeks. Ask your care team which radiation option(s) are best for you and what side effects to expect.

Types of radiation therapy used in DCIS include:

- **Whole breast radiation therapy (WBRT)** is used to treat the entire breast. Sometimes, additional treatments may be given to the tumor area. This is called a “boost.”

- **Partial breast irradiation (PBI)** is used to treat only the tumor area of the breast. Accelerated partial breast irradiation (APBI) is a higher dose given over a shorter period of time.

External beam radiation therapy

External beam radiation therapy (EBRT) uses a machine outside the body to aim radiation at the whole breast (WBRT) or only the tumor area of the breast (PBI).

Internal radiation

Internal radiation (brachytherapy) involves placing one or more small tubes into the tumor area of the breast. A small radioactive seed travels into the tube(s) and delivers radiation to the tumor area of the breast from inside the body. This type of radiation is used only for PBI.
Endocrine therapy

The endocrine system is made up of organs and tissues that produce hormones. Hormones are natural chemicals released into the bloodstream.

There are 4 hormones that might be targeted in endocrine therapy:

- **Estrogen** is made mainly by the ovaries, and also by other tissues in the body such as the fat tissue.
- **Progesterone** is made mainly by the ovaries.
- **Luteinizing hormone-releasing hormone (LHRH)** is made by a part of the brain called the hypothalamus. It tells the ovaries to make estrogen and progesterone and testicles to make testosterone. LHRH is also called gonadotropin-releasing hormone (GnRH).
- **Androgen** is made by the adrenal glands, testicles, and ovaries.

Hormones may cause breast cancer to grow. Endocrine therapy will stop your body from making hormones or it will block what hormones do in the body. This can help to reduce the risk of cancer returning.

Endocrine therapy is sometimes called hormone therapy. It is not the same as hormone replacement therapy used for menopause.

Types of endocrine therapy that might be used for DCIS:

- **Aromatase inhibitors (AIs)** stop a type of hormone called androgen from changing into estrogen by interfering with an enzyme called aromatase. They do not affect estrogen made by the ovaries. Non-steroidal aromatase inhibitors include anastrozole (Arimidex) and letrozole (Femara). Exemestane (Aromasin) is a steroidal aromatase inhibitor.
- **Estrogen receptor (ER) modulators** or anti-estrogens prevent hormones from binding to receptors.
- **Selective estrogen receptor modulators (SERMs)** block estrogen from attaching to hormone receptors. They include tamoxifen and toremifene (Fareston).
- **Selective estrogen receptor degraders (SERDs)** block and destroy estrogen receptors. Fulvestrant (Faslodex) and and elacestrant (Orserdu) are SERDs.
- **Gonadotropin-releasing hormone (GnRH) agonists** might be used to suppress ovarian hormone or testosterone production.

Those who want to have children in the future should be referred to a fertility specialist before starting endocrine therapy.

**Testosterone**

For those assigned male at birth whose bodies continue to make testosterone, endocrine therapy includes tamoxifen or an aromatase inhibitor with testosterone-suppressing therapy.
Treating DCIS  » Endocrine therapy

**Premenopause**

If you have menstrual periods, you are in premenopause. In premenopause, the ovaries are the main source of estrogen and progesterone. Menstrual periods may stop during treatment and for up to 2 years after treatment, but often returns in those 35 years of age and under.

Tamoxifen is the endocrine treatment for those in premenopause. Ovarian suppression or ablation is frequently considered for higher risk ER+ breast cancers.

**Menopause**

In menopause, the ovaries permanently stop producing hormones and menstrual periods stop. Estrogen and progesterone levels are low, but the adrenal glands, liver, and body fat continue to make small amounts of estrogen. If you don’t have periods, a test using a blood sample may be used to confirm your status. Cancer treatment can cause a temporary menopause.

Tamoxifen or an aromatase inhibitor is the endocrine treatment for those in menopause. Aromatase inhibitors include anastrozole (Arimidex), exemestane (Aromasin), and letrozole (Femara).

**Preventing pregnancy during treatment**

If you become pregnant during radiation therapy or endocrine therapy, it can cause serious birth defects. Use birth control without hormones. Condoms are an option. Speak to your care team about preventing pregnancy while being treated for DCIS.

**Finding a clinical trial**

**In the United States**

NCCN Cancer Centers  
NCCN.org/cancercenters

The National Cancer Institute (NCI)  
cancer.gov/about-cancer/treatment/clinical-trials/search

**Worldwide**

The U.S. National Library of Medicine (NLM)  
clinicaltrials.gov/

**Need help finding a clinical trial?**

NCI's Cancer Information Service (CIS)  
1.800.4.CANCER (1.800.422.6237)  
cancer.gov/contact
Clinical trials

A clinical trial is a type of medical research study. After being developed and tested in a laboratory, potential new ways of treating cancer need to be studied in people. If found to be safe and effective in a clinical trial, a drug, device, or treatment approach may be approved by the U.S. Food and Drug Administration (FDA).

Everyone with cancer should carefully consider all of the treatment options available for their cancer type, including standard treatments and clinical trials. Talk to your doctor about whether a clinical trial may make sense for you.

Phases

Most cancer clinical trials focus on treatment. Treatment trials are done in phases.

- **Phase I trials** study the dose, safety, and side effects of an investigational drug or treatment approach. They also look for early signs that the drug or approach is helpful.

- **Phase II trials** study how well the drug or approach works against a specific type of cancer.

- **Phase III trials** test the drug or approach against a standard treatment. If the results are good, it may be approved by the FDA.

- **Phase IV trials** study the long-term safety and benefit of an FDA-approved treatment.

Who can enroll?

Every clinical trial has rules for joining, called eligibility criteria. The rules may be about age, cancer type and stage, treatment history, or general health. These requirements ensure that participants are alike in specific ways and that the trial is as safe as possible for the participants.

Informed consent

Clinical trials are managed by a group of experts called a research team. The research team will review the study with you in detail, including its purpose and the risks and benefits of joining. All of this information is also provided in an informed consent form. Read the form carefully and ask questions before signing it. Take time to discuss with family, friends, or others whom you trust. Keep in mind that you can leave and seek treatment outside of the clinical trial at any time.

Start the conversation

Don’t wait for your doctor to bring up clinical trials. Start the conversation and learn about all of your treatment options. If you find a study that you may be eligible for, ask your treatment team if you meet the requirements. If you have already started standard treatment you may not be eligible for certain clinical trials. Try not to be discouraged if you cannot join. New clinical trials are always becoming available.
Frequently asked questions

There are many myths and misconceptions surrounding clinical trials. The possible benefits and risks are not well understood by many with cancer.

Will I get a placebo?
Placebos (inactive versions of real medicines) are almost never used alone in cancer clinical trials. It is common to receive either a placebo with a standard treatment, or a new drug with a standard treatment. You will be informed, verbally and in writing, if a placebo is part of a clinical trial before you enroll.

Do I have to pay to be in a clinical trial?
Rarely. It depends on the study, your health insurance, and the state in which you live. Your treatment team and the research team can help determine if you are responsible for any costs.

Supportive care
Supportive care will be specific to your needs. Supportive care is health care given to prevent, reduce, and relieve suffering, and to improve quality of life. Supportive care might include pain relief, emotional or spiritual support, financial aid, or family counseling. Tell your care team how you are feeling and about any side effects so they can be managed. Best supportive care, supportive care, and palliative care are often used interchangeably.

It is very important to take care of yourself by eating well, drinking plenty of fluids, exercising, and doing things that make you feel energized. Strength is needed to sustain you during treatment.

Difficulty eating
Sometimes side effects from surgery, cancer, or other treatments might cause you to feel not hungry or sick to your stomach (nauseated). Healthy eating is important during treatment. It includes eating a balanced diet, eating the right amount of food, and drinking enough fluids. A registered dietitian who is an expert in nutrition and food can help. Speak to your care team if you have trouble eating or maintaining your weight.

Distress
Depression, anxiety, and sleeping issues are common and are a normal part of cancer diagnosis. Talk to your care team and with those whom you feel most comfortable about how you are feeling. There are services, people, and medicine that can help you. Support and counseling services are available.

For more information, see NCCN Guidelines for Patients®: Distress Management – Distress During Cancer Care, available at NCCN.org/patientguidelines.

Fatigue
Fatigue is extreme tiredness and inability to function due to lack of energy. Fatigue may be caused by cancer or it may be a side effect of treatment. Let your care team know how you are feeling and if fatigue is getting in the way of doing the things you enjoy. Eating a balanced diet, exercise, yoga, acupuncture, and massage therapy can help. You might be referred to a nutritionist or dietitian to help with fatigue.
Lymphedema

Lymphedema is a condition in which extra lymph fluid builds up in tissues and causes swelling (edema). It may occur when part of the lymph system is damaged or blocked, such as during surgery to remove lymph nodes, or radiation therapy. Swelling usually develops slowly over time. It may develop during treatment or it may start years after treatment. If you have lymphedema, you may be referred to an expert in lymphedema management. The swelling may be reduced by exercise, massage, compression sleeves, and other means. Ask your care team about the ways to treat lymphedema.

Pain

Tell your care team about any pain or discomfort. You might meet with a palliative care specialist or with a pain specialist to manage pain.

Side effects

All cancer treatments can cause unwanted health issues called side effects. Side effects depend on many factors. These factors include the drug type and dose, length of treatment, and the person. Some side effects may be harmful to your health. Others may just be unpleasant.

Ask for a complete list of side effects of your treatments. Also, tell your treatment team about any new or worsening symptoms. There may be ways to help you feel better. There are also ways to prevent some side effects.

Keep a pain diary

A pain diary is a written record that helps you keep track of when you have pain, how bad it is, what causes it, and what makes it better or worse. Use a pain diary to discuss your pain with your care team. You might be referred to a specialist for pain management.

Include in your pain diary:

- The time and dose of all medicines
- When pain starts and ends or lessens
- Where you feel pain
- A description of your pain. Is it throbbing, sharp, tingling, shooting, or burning? Is it constant, or does it come and go?
- Does the pain change at different times of day? When?
- Does the pain get worse before or after meals? Does certain food or drink make it better?
- Does the pain get better or worse with activity? What kind of activity?
- Does the pain keep you from falling asleep at night? Does pain wake you up in the night?
- A rating of your pain from 0 (no pain) to 10 (worst pain you have ever felt)
- Does pain get in the way of you doing the things you enjoy?
Key points

- Treatment takes a team approach. Get to know your care team and help them get to know you.
- Surgery is the main treatment for DCIS.
- Radiation therapy (RT) uses high-energy radiation from x-rays (photons, electrons), protons, and other sources to kill cancer cells.
- Some breast cancers grow because of estrogen. These cancers are estrogen receptor-positive (ER+) and are often treated with endocrine therapy to reduce the risk of cancer recurrence.
- A clinical trial is a type of research that studies a treatment to see how safe it is and how well it works.
- Supportive care is health care that relieves symptoms caused by treatment and improves quality of life. Supportive care is always given.
- All cancer treatments can cause unwanted health issues called side effects. It is important for you to tell your care team about all your side effects so they can be managed.
- Eating a balanced diet, drinking enough fluids, exercise, yoga, and massage therapy can help manage side effects.
4

Your treatment options

32  Overview
32  Lumpectomy options
34  Mastectomy option
34  Endocrine therapy after lumpectomy
35  Follow-up care
36  Key points
DCIS is treated with surgery. It might be surgery to remove a lump (lumpectomy) or the breast (mastectomy) with or without lymph nodes. Radiation therapy usually follows a lumpectomy. The goal of treatment is to reduce the risk of DCIS progressing to invasive breast cancer. Together, you and your care team will choose a treatment plan that is best for you.

Overview

Ductal carcinoma in situ (DCIS) is treatable. Surgery is a central part of treatment for DCIS. Talk to your care team about what to expect from treatment. Your preferences about treatment are important. Make your wishes known. Treatment options are found in Guide 2.

There are 2 types of treatment:

- **Local therapy** focuses on the breast and armpit (axilla) only. It includes surgery and radiation therapy.

- **Systemic therapy** works throughout the body. It includes endocrine therapy. Chemotherapy is not used to treat DCIS.

The goal of treatment is to prevent DCIS from growing outside the duct into surrounding tissue. When cancer spreads into the surrounding tissue, it is called invasive breast cancer. Invasive breast cancer is breast cancer that has spread from the milk ducts or milk glands (lobules) into the breast tissue or to nearby lymph nodes.

**Lumpectomy options**

A lumpectomy is also known as breast-conserving surgery (BCS). It may or may not be followed by radiation therapy. Lymph node surgery is not done with a lumpectomy. You may have more than one surgery to ensure all of the cancer was removed.

A lumpectomy followed by radiation therapy is an option for many but not all with DCIS. This is not an option if you are pregnant, have some health issues, or the cancer is throughout the breast. The surgical margin must be cancer-free, called a negative surgical margin (R0). Lumpectomy options are described next.
Your treatment options » Lumpectomy options

Lumpectomy with whole breast radiation therapy

Most of your breast will be treated with radiation in whole breast radiation therapy (WBRT). Whole breast radiation will help to prevent the return of cancer. For every cancer that returns there is an equal chance of developing DCIS again or an invasive type of cancer. Many factors are used to determine risk of recurrence. Ask your care team if your risk of the cancer coming back is low or high. If it’s high, you may receive extra radiation called a boost.

Lumpectomy with partial breast irradiation

When radiation therapy (RT) is given only to the lumpectomy site, it is called partial breast irradiation (PBI). This is an option in some cases. You must have a low risk of the cancer returning. Surgical margins must be cancer-free. The size, grade, and other features of the tumor will be considered. Accelerated partial breast irradiation (APBI) therapy is a higher dose of radiation given over a shorter period of time.

Lumpectomy only

Treatment with a lumpectomy only (no radiation) is an option for a small group of people. You must have a low risk of the cancer coming back. Surgical margins must be cancer-free. The size, grade, and other features of the tumor will be considered.

Guide 2
Treatment options

Option 1

• Lumpectomy with whole breast radiation therapy (WBRT)
• Lumpectomy with WBRT and radiation boost

Option 2

• Lumpectomy with accelerated partial breast irradiation (APBI) or partial breast irradiation (PBI) (an option in some cases)

Option 3

• Lumpectomy only (not an option for most people)

Option 4

• Total mastectomy
• Total mastectomy with sentinel lymph node biopsy
• Flat closure or reconstruction after mastectomy
Mastectomy option

A total mastectomy or a simple mastectomy is a surgery that removes the whole breast. Chest muscle is not removed. A skin-sparing mastectomy removes the breast but not all the skin. A nipple-sparing mastectomy preserves the nipple-areola complex (NAC) and the skin. Not everyone is a candidate for nipple-sparing mastectomy. You might choose to have a flat closure or breast reconstruction after a mastectomy.

There are many reasons why a total mastectomy might be the best choice.

- Cancer may be found at the surgical margin.
- The tumor might be large, too big, or widespread.
- You may be at risk for a second cancer.
- You might have a health issue.
- You may want a mastectomy.
- You may not be able to receive radiation to the breast area.

Total mastectomy with or without sentinel lymph node biopsy

The surgeon may do a sentinel lymph node biopsy (SLNB) at the time of your surgery. Sentinel lymph nodes are the first nodes cancer cells are likely to have spread. An SLNB finds and removes a few of these nodes. The nodes are then tested for cancer. Once the breast is removed, an SLNB can’t be done. Instead, many lymph nodes would have to be removed to test for cancer. This is because a mastectomy permanently changes lymph flow and drainage. Therefore, if needed, an SLNB will be done at the time of a mastectomy, just in case there is a small area of invasive cancer in the breast.

Endocrine therapy after lumpectomy

Endocrine therapy is often given after a lumpectomy for cancers that are estrogen receptor-positive (ER+). This is given to reduce the risk of cancer returning. For treatment after breast-conserving surgery, see Guide 3.

Guide 3
Treatment after breast-conserving surgery (lumpectomy)

Consider endocrine therapy for 5 years for those with estrogen receptor-positive (ER+) DCIS if treated with:

- Breast-conserving surgery (lumpectomy) and radiation therapy
- Lumpectomy alone

Endocrine therapy options:

- For those in premenopause, tamoxifen
- For those in menopause, tamoxifen or aromatase inhibitor (AI)
Endocrine therapy

Endocrine therapy includes treatments that stop cancer growth caused by hormones. It is sometimes called hormone therapy. It is not the same as hormone replacement therapy.

Endocrine therapy may be given to help reduce the risk of developing a second breast cancer in those who were treated with:

- Breast-conserving surgery (lumpectomy) with radiation therapy
- Lumpectomy alone

There is more than one type of endocrine therapy. The type prescribed by your care team is partly based on if you have menstrual periods.

- Those who have menstrual periods are considered to be in premenopause. Tamoxifen is an option.
- Those whose menstrual periods have stopped for more than 12 months are considered to be in menopause. Tamoxifen or an aromatase inhibitor is an option. An aromatase inhibitor might be preferred if you are under 60 years of age or at risk for blood clots.

While taking endocrine therapy, it is important to have follow-up visits with your care team and seek regular preventative care with a dentist. Let your dentist know if you are taking any of these medicines. Let your doctor know about any planned dental procedures.

Medicine might be given to prevent bone loss and fractures while on endocrine therapy. A calcium and vitamin D supplement might be recommended, but talk to your doctor first.

Follow-up care

After treatment, you will receive follow-up care. It is important to keep any follow-up visits and imaging test appointments. Contact your doctor if you have any new or worsening symptoms.

Medical history and physical exam

An update of your medical history and a physical exam are part of follow-up care. Both should be done every 6 to 12 months for 5 years. Then once a year after 5 years of normal results.

Mammogram

A mammogram should be done every 12 months. The first one may be as soon as 6 months after breast-conserving treatment. Mammograms aren't needed if you had both breasts removed to reduce your cancer risk.

Lowering your risk

There are things you can do to lower your chance of developing breast cancer in the future. Changes in your lifestyle include eating a mostly plant-based diet, exercising, limiting alcohol, and quitting smoking. Your care team can offer information and support on how to lower your risk.
Key points

➤ Ductal carcinoma in situ (DCIS) is treatable. The goal of treatment is to reduce the risk of DCIS progressing to invasive breast cancer.

➤ Treatment for DCIS is usually a combination of surgery and radiation therapy followed by endocrine therapy.

➤ Surgery options include a lumpectomy or mastectomy.

➤ A lumpectomy is also called breast-conserving surgery (BCS).

➤ A total mastectomy or a simple mastectomy is a surgery that removes the whole breast. Lymph node surgery is often done with a mastectomy.

➤ A skin-sparing mastectomy removes the breast but not all the skin.

➤ A nipple-sparing mastectomy preserves the nipple-areola complex (NAC) and the skin. Not everyone is a candidate for nipple-sparing mastectomy.

➤ Local therapy focuses on the breast and armpit (axilla) only. It includes surgery and radiation therapy.

➤ Systemic therapy works throughout the body. It includes endocrine therapy. Chemotherapy is not used to treat DCIS.

➤ Lifestyle changes, endocrine therapy, and surgery help to reduce the risk of future breast cancer.

➤ Follow-up care includes medical history, physical exams, and mammograms.
5
The breast after surgery

38 Volume displacement
39 Flat closure
39 Breast reconstruction
40 Nipple replacement
41 What to consider
41 Key points
The look of your breast after surgery will depend on the type of surgery, the amount of tissue removed, and other factors such as your body type, age, and size and shape of the area before surgery. You might consider speaking with a plastic surgeon before surgery. This chapter offers more information on volume displacement, flat closure, and breast reconstruction.

The recovery time for each procedure differs. This can affect your ability to return to work or participate in activities. You might consider speaking with a plastic surgeon before surgery to discuss your options and what to expect.

Volume displacement

With a lumpectomy, most people have a scar with some volume loss. However, if you need a large lumpectomy and your surgeon thinks your breast will look more abnormal afterwards, your breast may be able to be re-shaped at the time of surgery. This procedure is called volume displacement or oncoplasty. Only a limited number of cancer centers perform this procedure. It is often done by the cancer surgeon or plastic surgeon right after the lumpectomy. The surgeon will shift the remaining breast tissue to fill the space left by the removed tumor.

If volume displacement is planned, a larger piece of your breast will need to be removed. Despite a larger piece being removed, the natural look of your breast will be kept.
You may not like the results of the volume displacement. In this case, breast revision surgery may help. This surgery is done by a plastic surgeon. A second volume displacement may be an option, too. Another option is to get breast implants or mastectomy with reconstruction.

Flat closure

In a total mastectomy with a flat closure, the entire breast, including nipple, extra skin, fat, and other tissue in the breast area are removed. The remaining skin is tightened and sewn together. No breast mound is created and no implant is added. The scar will be slightly raised and differ in color than the surrounding skin. A flat closure is not completely flat or smooth. The end result varies from person to person. Ask to look at “after” pictures from flat closures so you know what to expect.

You might decide to have a flat closure procedure at a later time or after having breast implants removed. Talk to your care team to learn more.

Breast reconstruction

Breast reconstruction is surgery to rebuild the shape and look of the breast after a mastectomy. In many cases, breast reconstruction involves a staged approach. It might require more than one procedure.

You may have a choice as to when breast reconstruction is done. Immediate reconstruction is finished within hours after removing the breast. Delayed reconstruction can occur months or years after the cancer surgery. Reconstruction can also be done in a staged fashion, with part of the reconstruction done at the time of the original cancer surgery, and finished with another surgery at a later time. A plastic surgeon performs breast reconstruction.

Breasts can be reconstructed with implants and flaps. All methods are generally safe, but as with any surgery, there are risks. Ask your treatment team for a complete list of side effects.

Implants

Breast implants are small bags filled with salt water, silicone gel, or both. They are placed under the breast skin or muscle to look like a new breast following a mastectomy. A balloon-like device, called an expander, may be used first to stretch out tissue. It will be placed under your skin or muscle and enlarged every few weeks for 2 to 3 months. When your skin is stretched to the proper size, you will have surgery to place the final implant.

Implants have a small risk of leaking or causing other issues. You may feel pain from the implant or expander. Scar tissue or tissue death can occur. Textured implants can cause breast implant-associated anaplastic large cell lymphoma (BIA-ALCL), a type of cancer.

Flaps

Sometimes breast fullness can be recreated after a skin-sparing mastectomy. In a skin-sparing mastectomy, breast tissue is removed from underneath the skin. The nipple remains intact, if possible. The remaining skin flaps are used to create a breast mound. This technique does not use implants or skin transferred from other parts of the body and may be completed in a single surgery. This technique, called a Goldilocks mastectomy, is best suited for those
with larger breasts who are willing to have much smaller breasts as a result.

Breasts can be remade using tissue from other parts of your body, known as “flaps.” These flaps are taken from the abdomen, buttocks, thigh, or from under the shoulder blade. Some flaps are completely removed and then sewn in place. Other flaps stay attached to your body but are slid over and sewn into place.

There are several risks associated with flaps, including death of fat in the flap, which can cause lumps. A hernia may result from muscle weakness. Problems are more likely to occur among those who have diabetes or who smoke.

**Implants and flaps**

Some breasts are reconstructed with both implants and flaps. This method may give the reconstructed breast more volume to match the other breast. For any reconstruction, you may need surgery on your remaining breast to match the two breasts in size and shape.

Nipple replacement

Like your breast, a nipple can be remade. To rebuild a nipple, a plastic surgeon can use surrounding tissues. Also, nipples can be remade with tissue from the thigh or other nipple. Tissue can be darkened with a tattoo to look more like a nipple. It is important to note that while you can remake something to look like a nipple, it will not have the sensation of your real nipple. Also, a tattoo can be done to look like a nipple without having to take tissue from another part of the body.

Tattoo

Removed nipples can be remade with body tissue and/or tattooing.
What to consider

Some things to consider when deciding to have flat closure or reconstruction after mastectomy:

- **Your desire** – You may have a strong feeling towards flat closure or one form of reconstruction after being given the options. Breast reconstruction should be a shared decision between you and your care team. Make your wishes known.

- **Health issues** – You may have health issues such as diabetes or a blood disorder that might affect or delay healing, or make longer procedures unsafe.

- **Tobacco use** – Smoking delays wound healing and can cause mastectomy flap death (necrosis), nipple-areola complex (NAC) necrosis in a nipple-sparing mastectomy, infection, and failure of implant-based reconstruction. In free flap reconstruction, smoking increases the risk of complications. You are encouraged to stop smoking prior to reconstruction.

- **Breast size and shape** – There are limits to the available sizes of breast implants. Very large breasts or breasts that lack tone or droop (called ptosis) might be difficult to match. Breast reduction surgery might be an option.

- **Body mass index (BMI)** – Those with an elevated BMI have increased risk of infections and complications with breast reconstruction.

Key points

- **Volume displacement** is a shifting of the breast tissue to fill the gap left by a lumpectomy.

- **Flat closure** is done after a mastectomy in which the skin is tightened and sewn together without the addition of a breast implant.

- **Breast reconstruction** is surgery to rebuild the shape and look of the breast.

- **Breasts that are fully removed in a mastectomy** can be remade with breast implants, flaps, or both.

- **Removed nipples** can be remade with body tissue and/or tattooing.

6 Making treatment decisions

43 It’s your choice
43 Questions to ask
50 Resources
Making treatment decisions » It's your choice » Questions to ask

It's your choice

In shared decision-making, you and your team share information, discuss the options, and agree on a treatment plan. It starts with an open and honest conversation between you and your care team.

Treatment decisions are very personal. What is important to you may not be important to someone else.

Some things that may play a role in your decision-making:

- What you want and how that might differ from what others want
- Your religious and spiritual beliefs
- Your feelings about certain treatments
- Your feelings about pain or side effects
- Cost of treatment, travel to treatment centers, and time away from school or work
- Quality of life and length of life
- How active you are and the activities that are important to you

Think about what you want from treatment. Discuss openly the risks and benefits of specific treatments and procedures. Weigh options and share concerns with your care team. If you take the time to build a relationship with your doctor, it will help you feel supported when considering options and making treatment decisions.

Second opinion

It is normal to want to start treatment as soon as possible. While cancer can’t be ignored, there is time to have another doctor review your test results and suggest a treatment plan. This is called getting a second opinion, and it’s a normal part of cancer care. Even doctors get second opinions!

Things you can do to prepare:

- Check with your insurance company about its rules on second opinions. There may be out-of-pocket costs to see doctors who are not part of your insurance plan.
- Make plans to have copies of all your records sent to the doctor you will see for your second opinion.

Support groups

Many people diagnosed with cancer find support groups to be helpful. Support groups often include people at different stages of treatment. Some people may be newly diagnosed, while others may be finished with treatment. If your hospital or community doesn’t have support groups for people with cancer, check out the websites listed in this book.

Questions to ask

Possible questions to ask your doctors are listed on the following pages. Feel free to use these questions or come up with your own. Be clear about your goals for treatment and find out what to expect from treatment.
Questions about testing and diagnosis

1. What tests will I have? How often will they be repeated?
2. Will my insurance pay for this test?
3. What will you do to make me comfortable during testing?
4. What if I am pregnant or want to become pregnant in the near future?
5. When will I have a biopsy?
6. What are the risks with a biopsy?
7. How will my biopsy be performed?
8. What else might be done during the biopsy?
9. How soon will I know the results and who will explain them to me?
10. How can I get a copy of the pathology report and other test results?
Questions about your care team’s experience

1. What is your experience treating DCIS?
2. What is the experience of those on your team?
3. Do you only treat DCIS? What else do you treat?
4. How many people like me (of the same age, gender, race) have you treated?
5. Will you be consulting with experts to discuss my care? Whom will you consult?
6. How many procedures like the one you’re suggesting have you done?
7. Is this treatment a major part of your practice?
8. How many of your patients have had complications? What were the complications?
9. How many breast cancer surgeries have you done?
10. Who will manage my day-to-day care?
Questions about options

1. What will happen if I do nothing?
2. Which option is proven to work best for my cancer, age, overall health, and other risk factors?
3. What are the possible complications and side effects? Are any life-threatening?
4. What can be done to prevent or relieve the side effects of treatment?
5. Am I a candidate for a clinical trial?
6. Can I join a clinical trial at any time?
7. What decisions must be made today?
8. Is there a social worker or someone who can help me decide about treatment?
9. Is there a hospital or treatment center you can recommend for breast cancer treatment?
10. Can I go to one hospital for surgery and a different center for radiation therapy?
Questions about treatment

1. Which treatment(s) do you recommend and why?
2. Does the order of treatment matter?
3. When will I start treatment?
4. How long will treatment take?
5. What should I expect from treatment?
6. What will you do to make me comfortable during treatment?
7. How much will my insurance pay for treatment?
8. Are there programs to help me pay for treatment?
9. What are the chances my cancer will return after treatment?
10. I would like a second opinion. Is there someone you can recommend?
Questions about surgery

1. How much of my breast will be removed?
2. What will my breast look like after surgery?
3. What lymph nodes might be removed during surgery?
4. How long will recovery take and what should I expect?
5. What are the chances you can remove the whole tumor with a negative margin?
6. How long will it take me to recover from surgery?
7. When will I be able to return to work or normal activities after surgery?
8. How much pain will I be in and what will be done to manage my pain?
9. What complications can occur from this surgery?
10. What options are available if I do not like the look of my breast after surgery?
Questions about radiation therapy

1. What type of radiation therapy (RT) will I have?
2. What will you target?
3. What is the goal of this RT?
4. How many treatment sessions will I require?
5. Can you do a shorter course of RT?
6. Do you offer this type of RT here? If not, should I be referred to someone who does?
7. What side effects can I expect from RT?
8. Should I eat or drink before RT?
9. Will I be given medicine to help me relax during RT?
10. What should I wear?

Words to know

**accelerated partial breast irradiation (APBI)**
Treatment with radiation to the part of the breast with cancer. A higher dose is given over a shorter period of time compared to whole breast radiation therapy.

**anti-estrogen**
A drug that stops estrogen from attaching to cells.

**areola**
A darker, round area of skin on the breast around the nipple.

**aromatase inhibitor (AI)**
A drug that lowers the level of estrogen in the body.

**bilateral diagnostic mammogram**
Pictures of the insides of both breasts that are made from a set of x-rays.

**biopsy**
A procedure that removes fluid or tissue samples to be tested for a disease.

**boost**
An extra dose of radiation to a specific area of the body.

**breast-conserving surgery (BCS)**
A cancer treatment that includes removing a breast lump.

**breast implant**
A small bag filled with salt water, gel, or both that is used to remake breasts.

**breast reconstruction**
An operation that creates new breasts.

**cancer stage**
A rating of the outlook of a cancer based on its growth and spread.

**carcinoma**
A cancer of cells that line the inner or outer surfaces of the body.

**chest wall**
The layer of muscle, bone, and fat that protects the vital organs.

**clinical breast exam (CBE)**
Touching of a breast by a health expert to feel for diseases.

**clinical stage (c)**
The rating of the extent of cancer before treatment is started.

**clinical trial**
A type of research that assesses health tests or treatments.

**connective tissue**
Supporting and binding tissue that surrounds other tissues and organs.

**contrast**
A substance put into your body to make clearer pictures during imaging tests.

**core needle biopsy (CNB)**
A procedure that removes tissue samples with a hollow needle. Also called core biopsy.

**diagnostic bilateral mammogram**
Pictures of the insides of both breasts that are made from a set of x-rays.

**duct**
A tube-shaped structure through which milk travels to the nipple.
ductal carcinoma in situ (DCIS)
A breast cancer that has not grown outside the breast ducts.

endocrine therapy
A cancer treatment that stops the making or action of estrogen. Also called hormone therapy.

estrogen
A hormone that plays a role in breast development.

estrogen receptor (ER)
A protein inside cells that binds to estrogen.

estrogen receptor-negative (ER-)
A type of breast cancer that doesn’t use estrogen to grow.

estrogen receptor-positive (ER+)
A type of breast cancer that uses estrogen to grow.

fine-needle aspiration (FNA)
A procedure that removes tissue samples with a very thin needle.

flat closure
Procedure done after a mastectomy in which the skin is tightened and sewn together without the addition of a breast implant.

gene
Coded instructions in cells for making new cells and controlling how cells behave.

genetic counseling
Expert guidance on the chance for a disease that is passed down in families.

hereditary breast cancer
Breast cancer likely caused by abnormal genes passed down from biological parent to child.

histology
The structure of cells, tissue, and organs as viewed under a microscope.

hormone
A chemical in the body that triggers a response from cells or organs.

immunohistochemistry (IHC)
A lab test of cancer cells to find specific cell traits involved in abnormal cell growth.

invasive breast cancer
The growth of breast cancer into the breast’s supporting tissue (stroma).

lobule
A gland in the breast that makes breast milk.

lobular carcinoma in situ (LCIS)
A benign (non-cancerous) condition in which abnormal cells are found in the lobules of the breast.

lumpectomy
An operation that removes a small breast cancer tumor. Also called breast-conserving surgery.

lymph
A clear fluid containing white blood cells.

lymph node
A small, bean-shaped disease-fighting structure.

lymphadenopathy
Lymph nodes that are abnormal in size or consistency.

lymphatic system
Germ-fighting network of tissues and organs that includes the bone marrow, spleen, thymus, lymph nodes, and lymphatic vessels. Part of the immune system.
lymphedema
Swelling in the body caused by a buildup of fluid called lymph.

magnetic resonance imaging (MRI)
A test that uses radio waves and powerful magnets to make pictures of the insides of the body.

mastectomy
An operation that removes the whole breast.

medical history
A report of all your health events and medications.

menopause
The point in time 12 months after a last menstrual period.

mutation
An abnormal change.

nipple-areola complex (NAC)
The ring of darker breast skin is called the areola. The raised tip within the areola is called the nipple.

noninvasive breast cancer
Breast cancer that has not grown into tissue from which it can spread.

palpable adenopathy
Lymph nodes that feel abnormal in size or consistency.

partial breast irradiation
Treatment with radiation that is received at the site of the removed breast tumor.

pathologic stage (p)
A rating of the extent of cancer given after examining tissue removed during surgery.

pathologist
A doctor who’s an expert in testing cells and tissue to find disease.

postmenopause
The state of having no more menstrual periods.

premenopause
The state of having menstrual periods.

primary tumor
The first mass of cancer cells.

prognosis
The likely course and outcome of a disease based on tests.

radiation therapy (RT)
A treatment that uses high-energy rays. Also called radiotherapy.

recurrence
The return of cancer after a cancer-free period.

sentinel lymph node (SLN)
The first lymph node to which cancer cells spread after leaving a tumor.

sentinel lymph node biopsy (SLNB)
An operation to remove the disease-fighting structures (lymph nodes) to which cancer first spreads. Also called sentinel lymph node dissection.

side effect
An unhealthy or unpleasant physical or emotional response to treatment.

skin-sparing mastectomy
An operation that removes all breast tissue but saves as much breast skin as possible.

supportive care
Health care that includes symptom relief but not cancer treatment. Also called palliative care or best supportive care.
Words to know

**surgical margin**
The normal-looking tissue around a tumor removed during an operation.

**systemic therapy**
Drug treatment that works throughout the body.

**total mastectomy**
An operation that removes the entire breast with an aesthetic flat closure. Also called simple mastectomy.

**ultrasound**
A test that uses sound waves to take pictures of the inside of the body.

**vacuum-assisted core biopsy (VACB)**
A procedure in which a small sample of tissue is removed from the breast with the aid of a vacuum device.

**volume displacement**
A method to shift breast tissue during an operation to fill a space left from a lumpectomy.

**whole breast radiation therapy (WBRT)**
Treatment with radiation of the entire breast.

NCCN Contributors

This patient guide is based on the NCCN Clinical Practice Guidelines in Oncology (NCCN Guidelines®) for Breast Cancer Version 4.2023. It was adapted, reviewed, and published with help from the following people:

Dorothy A. Shead, MS  
Senior Director  
Patient Information Operations

Tanya Fischer, MEd, MSLIS  
Senior Medical Writer

Laura Phillips  
Graphic Design Specialist

The NCCN Guidelines® for Breast Cancer Version 4.2023 were developed by the following NCCN Panel Members:

William J. Gradishar, MD/Chair  
Robert H. Lurie Comprehensive Cancer Center of Northwestern University

Meena S. Moran, MD/Vice-Chair  
Yale Cancer Center/Smilow Cancer Hospital

Jame Abraham, MD  
Case Comprehensive Cancer Center/University Hospitals Seidman Cancer Center and Cleveland Clinic Taussig Cancer Institute

Vandana Abramson, MD  
Vanderbilt-Ingram Cancer Center

*Rebecca Aft, MD, PhD  
Siteman Cancer Center at Barnes-Jewish Hospital and Washington University School of Medicine

Doreen Agnese, MD  
The Ohio State University Comprehensive Cancer Center - James Cancer Hospital and Solove Research Institute

Kimberly H. Allison, MD  
Stanford Cancer Institute

*Bethany Anderson, MD  
University of Wisconsin  
Carbone Cancer Center

Harold J. Burstein, MD, PhD  
Dana-Farber/Brigham and Women’s Cancer Center

Helen Chew, MD  
UC Davis Comprehensive Cancer Center

Chau Dang, MD  
Memorial Sloan Kettering Cancer Center

Anthony D. Elias, MD  
University of Colorado Cancer Center

Sharon H. Giordano, MD, MPH  
The University of Texas  
MD Anderson Cancer Center

Matthew P. Goetz, MD  
Mayo Clinic Comprehensive Cancer Center

Lori J. Goldstein, MD  
Fox Chase Cancer Center

Sara A. Hurvitz, MD  
UCLA Jonsson Comprehensive Cancer Center

Rachel C. Jankowitz, MD  
Abramson Cancer Center at the University of Pennsylvania

*Sara H. Javid, M
